

Chapter 1: Moles and equations

Homework marking scheme

In these questions the main formulae used are $n = \frac{V}{24000}$ for gases and $n = \frac{m}{A_r}$ for solids.

- 1 a i** $n(\text{H}_2) = \frac{300}{24000} = 1.25 \times 10^{-2} \text{ mol}$ [1]
- ii** $n(\text{Ca}) = n(\text{H}_2) = 1.25 \times 10^{-2} \text{ mol}$ [1]
- iii** 1 mark for formula $A_r = \frac{m}{n}$ [1]
- The second mark is for using the values and calculating the A_r ;
- $$A_r = \frac{0.52}{1.25 \times 10^{-2}} = 41.6$$
- [1]
- b i** $n(\text{HCl}) = 25.8 \times 10^{-3} \times 1$ (using $n = c \times V$) [1]
- ii** From equation, $n(\text{Ca}(\text{OH})_2) = n(\text{Ca}) = \frac{1}{2} n(\text{HCl}) = 1.29 \times 10^{-2}$
1 mark for the relationship and 1 mark for the calculation [2]
- iii** 1 mark is for $A_r = \frac{m}{n}$
- The second mark is for using the values and calculating the A_r ;
- $$A_r = \frac{0.52}{1.29 \times 10^{-2}} = 40.3$$
- [2]
- c** $A_r = \frac{(40 \times 96.97) + (42 \times 0.64) + (43 \times 0.15) + (44 \times 2.06) + (46 \times 0.003) + (48 \times 0.19)}{100}$
 $= 40.12$
1 mark for formula, 1 mark for 40.1 and 1 mark for the second decimal place [3]
- d i** The titration is more accurate because it gave a result closer to the actual. [1]
- ii** Impurities on the sample of the calcium metal, such as calcium oxide. [1]
- 2 a** The relative atomic mass is the weighted average mass of the (naturally occurring) atoms of an element [1]
compared with 1/12th [1]
the mass of an atom of carbon-12 [1]
- b** The isotope with a relative isotopic mass of 7 [1]
because the relative atomic mass is nearer 7 than 6 [1]
and it is the **weighted** average that is used [1]
- c i** $2\text{Li}(\text{s}) + 2\text{H}_2\text{O}(\text{l}) \rightarrow 2\text{LiOH}(\text{aq}) + \text{H}_2(\text{g})$
1 mark for the correct symbols and formulae, 1 mark for the balancing [2]
- ii** $n(\text{H}_2) = \frac{V_{\text{gas}}}{24000} = \frac{245}{24000} = 1.02 \times 10^{-2} \text{ mol}$ [1]
 $n(\text{Li}) = 2 \times n(\text{H}_2) = 2 \times 1.02 \times 10^{-2} = 2.04 \times 10^{-2} \text{ mol}$ [1]
 $A_r = \frac{m}{n} = \frac{0.15}{2.04 \times 10^{-2}}$ [1]
 $= 7.35 \text{ (g mol}^{-1}\text{)}$ [1]

- d i** Readings are 22.00; 21.55; 22.80; 21.55, use 21.55 cm³
1 mark for all correct and 1 mark for giving all to 2 decimal places [2]
- ii** $n(\text{Li}) = n(\text{LiOH}) = n(\text{HCl})$ [1]
 $n(\text{Li}) = 21.55 \times 10^{-3} \times 0.100 = 2.16 \times 10^{-3} \text{ mol}$ [1]
 This is one-tenth of the total amount of lithium hydroxide and therefore lithium (25 cm³ out of total of 250 cm³) [1]
 Therefore, total amount of lithium = $2.16 \times 10^{-2} \text{ mol}$ [1]
 $A_r(\text{Li}) = \frac{m}{n} = \frac{0.15}{2.16 \times 10^{-2}} = 6.94 \text{ (g mol}^{-1}\text{)}$ [1]
- iii** volumetric flask [1]
 pipette [1]
- 3 a** $2\text{NaHCO}_3(\text{s}) \rightarrow \text{Na}_2\text{CO}_3(\text{s}) + \text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{l})$ [1]
- b i** $n(\text{NaHCO}_3) = \frac{m}{M_r} = \frac{0.42}{84}$ [1]
 $= 5 \times 10^{-3} \text{ mol}$ [1]
- ii** $n(\text{CO}_2) = \frac{48}{24000} = 2 \times 10^{-3} \text{ mol}$ [1]
- iii** The actual number of moles of sodium hydrogencarbonate can be found from the equation:
 $n(\text{NaHCO}_3) = 2 \times n(\text{CO}_2) = 4 \times 10^{-3} \text{ mol}$
 1 mark for using the equation and 1 mark for the calculation [2]
- iv** Percentage purity = actual number of moles of NaHCO₃/number of moles weighed out
 $= \frac{0.004}{0.005} \times 100\% = 80\%$
 1 mark for the relationship and 1 mark for the calculation [2]
- c** $n(\text{Na}_2\text{CO}_3) = \frac{1}{2} \times n(\text{NaHCO}_3)$ [1]
 $= \frac{1}{2} \times 4 \times 10^{-3} = 2 \times 10^{-3} \text{ mol}$ [1]
- d** $n(\text{HCl}) = 2 \times n(\text{Na}_2\text{CO}_3) = 4 \times 10^{-3} \text{ mol}$ [1]
 $V(\text{HCl})_1 = \frac{n}{C} = \frac{4 \times 10^{-3}}{0.2} = 20 \times 10^{-3} \text{ dm}^3 (= 20 \text{ cm}^3)$ [1]
