### 21.0 Thermal Energy

## AQA A2 Specification

| Lessons | Topics |
| :---: | :--- |
| $1 \& 2$ | Thermal energy <br> Calculations involving change of energy. <br> For a change of temperature; $Q=m c \Delta \theta$ where $c$ is specific heat capacity. <br> For a change of state; $Q=m l$ where $l$ is specific latent heat. |

## Thermal energy

## What is thermal energy?

- internal energy.
- It is equal to the sum of the random distribution of the kinetic and potential energies of the object's molecules.
- Molecular kinetic energy increases with temperature.
- Potential energy increases if an object changes state from solid to liquid or liquid to gas.

If the internal energy is represented by the potential energy and kinetic energy in the bonds of any material, why do gases not have potential energy?

In a gas, the molecules are so far apart that there are no intermolecular interactions. So there is no potential energy. Therefore the energy is entirely kinetic

## Heat

Heat is energy that flows from a high temperature object to a lower temperature object

When something absorbs heat its internal energy (or the energy of its atoms/molecules) increases
When something releases heat its internal energy decreases

What is the SI unit of heat?

What two things occur when an object absorbs or releases heat energy?

Joule, J
-The temperature will change (which is why they expand/contract, due to changes in molecular motion)
-The object (or part of it) will change phase (solid, liquid, gas)

## Temperature

## What is temperature?

Temperature is a measure of the degree of hotness of a substance.

Heat energy normally moves from regions of higher to lower temperature.

What is the condition for thermal equilibrium?
Two objects are said to be in thermal
equilibrium with each other if there is not net transfer of heat energy between them.

This will only occur if both objects are at the same temperature.

## Absolute Zero (OK)

Absolute zero is the lowest possible temperature where objects have minimal KE

## Absolute zero

The graph opposite shows that the pressure of all gases will fall to zero at absolute zero which is approximately $-273^{\circ} \mathrm{C}$.

What effect will this have on atomic spacing?

hot solid
cooling

cool solid

## Temperature Scales

A temperature scale is defined by two fixed points which are standard degrees of hotness that can be accurately reproduced.

What fixed points might be used?

Celsius Scale (symbol: $\boldsymbol{\theta}$ - unit: ${ }^{\circ} \mathrm{C}$ )
Fixed points:
ice point, $0^{\circ} \mathrm{C}$ : the temperature of pure melting ice
steam point, $100^{\circ} \mathrm{C}$ : the temperature at which pure water boils at standard atmospheric pressure

## The Absolute scale

## Fixed points:

absolute zero, OK: the lowest possible temperature. This is equal to $-273.15^{\circ} \mathrm{C}$
triple point of water, 273.16 K : the temperature at which pure water exists in thermal equilibrium with ice and water vapour. This is equal to $0.01^{\circ} \mathrm{C}$.

## Converting between scales

A change of one degree celsius is the same as a change of one kelvin.

Therefore:
${ }^{\circ} \mathrm{C}=\mathrm{K}$ - 273.15 $\mathrm{OR} K={ }^{\circ} \mathrm{C}+273.15$

Kelvin, K

## Complete (use $273 \mathrm{~K}=0^{\circ} \mathrm{C}$ ):

| Situation | Celsius ( ${ }^{\circ} \mathbf{C}$ ) | Absolute (K) |
| :---: | :---: | :---: |
| Boiling water | 100 |  |
| Vostok Antarctica 1983 | -89 |  |
| Average Earth surface |  | 288 |
| Gas flame | 1500 |  |
| Sun surface |  |  |

## Answers:

| Situation | Celsius ( ${ }^{\circ} \mathbf{C}$ ) | Absolute (K) |
| :---: | :---: | :---: |
| Boiling water | 100 | 373 |
| Vostok Antarctica 1983 | -89 | 184 |
| Average Earth surface | 15 | 288 |
| Gas flame | 1500 | 1773 |
| Sun surface | 5727 | 6000 |

## Manometers

### 11.2 Heating

If we heat some material so that its temperature rises, the amount of energy we must supply depends on three things:

- the mass $m$ of the material we are heating
- the temperature change $\Delta \theta$ we wish to achieve
- the material itself.

Some materials are easier to heat than others. It takes more energy to raise the temperature of 1 kg of water by $1^{\circ} \mathrm{C}$ than to raise the temperature of 1 kg of alcohol by the same amount.
We can represent this in an equation. Th e amount of energy $E$ that must be supplied is given by:

$$
E=m c \Delta \theta
$$

where $c$ is the specifi $c$ heat capacity of the material.

### 11.2 The specific heat capacity of a substance

The specific heat capacity of a substance is the energy required per unit mass of the substance to raise the temperature by 1 K (or $1^{\circ} \mathrm{C}$ ).

Table 1 shows some values of specific heat capacity measured at $0^{\circ} \mathrm{C}$.

| Substance | $c / \mathrm{Jkg}^{-1} \mathrm{~K}^{-1}$ |
| :--- | ---: |
| aluminium | 880 |
| copper | 380 |
| lead | 126 |
| glass | $500-680$ |
| ice | 2100 |
| water | 4180 |
| sea water | 3950 |
| ethanol | 2500 |
| mercury | 140 |

## Examples of SHC

| Substance | SHC (Jkg $\left.{ }^{-1} \mathbf{K}^{\mathbf{1}}\right)$ | Substance | SHC (Jkg $\left.{ }^{\mathbf{- 1}}{ }^{\mathbf{- 1}}\right)$ |
| :---: | :---: | :---: | :---: |
| water | 4200 | helium | 5240 |
| ice or steam | 2100 | glass | 700 |
| air | 1000 | brick | 840 |
| hydrogen | 14300 | wood | 420 |
| gold | 129 | concrete | 880 |
| copper | 385 | rubber | 1600 |
| aluminium | 900 | brass | 370 |
| mercury | 140 | paraffin | 2130 |

## Complete

| Substance | Mass | SHC <br> $\left(\mathbf{J k g}^{-1} \mathrm{~K}^{-1}\right)$ | Temperature <br> change | Energy (J) |
| :---: | :---: | :---: | :---: | :---: |
| water | 4 kg | 4200 | $50^{\circ} \mathrm{C}$ |  |
| gold | 4 kg | 129 |  | 25800 |
| air | 4 kg |  | 50 K | 200000 |
| glass |  | 700 | $40^{\circ} \mathrm{C}$ | 84000 |
| hydrogen | 5 mg | 14300 | 400 K |  |
| brass | 400 g | 370 | $50^{\circ} \mathrm{C}$ to K | 14800 |

## Answers

| Substance | Mass | SHC <br> $\left(\mathbf{J k g}^{-1} \mathrm{~K}^{-1}\right)$ | Temperature <br> change | Energy (J) |
| :---: | :---: | :---: | :---: | :---: |
| water | 4 kg | 4200 | $50^{\circ} \mathrm{C}$ | 840000 |
| gold | 4 kg | 129 | $50^{\circ} \mathrm{C}$ | 25800 |
| air | 4 kg | 1000 | 50 K | 200000 |
| glass | 3 kg | 700 | $40^{\circ} \mathrm{C}$ | 84000 |
| hydrogen | 5 mg | 14300 | 400 K | 28.6 |
| brass | 400 g | 370 | $50^{\circ} \mathrm{C}$ to 223 K | 14800 |

## Question

Calculate the heat energy
required to raiser the
temperature of a copper can
(mass 50 g ) containing $200 \mathrm{~cm}^{3}$
of water from 20 to $100^{\circ} \mathrm{C}$

```
E=mc\Delta0
```

For the copper can:
$E=0.05 \times 385 \times(100-20)=1540 \mathrm{~J}$

For the water:
Density of water $=1 \mathrm{~g} \mathrm{~cm}^{-3}$.
Therefore mass of water $=200 \mathrm{~g}$.
$E=0.200 \times 4200 \times 80=67200 \mathrm{~J}$

## Calorimetry

A method to measure specific heat capacity that is based on:

The principle of conservation of energy
The known specific heat capacity for
water ( $1000 \mathrm{cal} / \mathrm{kg}{ }^{\circ} \mathrm{C}$ or $4186 \mathrm{~J} / \mathrm{kg}{ }^{\circ} \mathrm{C}$ )

Jalorimeter

## The Process:

- A heated object is placed into a thermally isolated container containing a known amount of water

$$
Q_{\text {net }}=Q_{\text {gained by water }}+Q_{\text {gained by object }}=0
$$

- Object and liquid reach thermal equilibrium:

$$
Q_{\text {gained by water }}=Q_{\text {lost by object }}\left\{=-Q_{\text {gained by object }}\right\}
$$

- The final temperature of the object/water is used to determine the specific heat of the object

## Measuring SHC (metal solid)

## Measuring SHC (metal solid)

- Metal has known mass, $m$.
- Initial temperature $\theta_{1}$ measured.
- Heater switched on for a known time, $\boldsymbol{t}$ during which the average p.d., $V$ and electric current $I$ is measured.
- Final maximum temperature $\theta_{2}$ measured.
- Energy supplied $=V I t=m c\left(\theta_{2}-\theta_{1}\right)$
- Hence: $c=\operatorname{VIt} / m\left(\theta_{2}-\theta_{1}\right)$

## Example calculation

Metal mass, $m .=500 \mathrm{~g}=0.5 \mathrm{~kg}$
Initial temperature $\theta_{1}=20^{\circ} \mathrm{C}$
Heater switched on for time, $t=5$ minutes $=300 \mathrm{~s}$.
p.d., $V=12 \mathrm{~V}$; electric current $I=2.0 \mathrm{~A}$

Final maximum temperature $\theta_{2}=50^{\circ} \mathrm{C}$
Energy supplied $=V I t=12 \times 2 \times 300=7$ 200J
$=m c\left(\theta_{2}-\theta_{1}\right)=0.5 \times c \times(50-30)=10 c$
Hence: $c=7200 / 10$
$=720 \mathrm{~J} \mathrm{~kg}^{-1}{ }^{0} \mathrm{C}^{-1}$

## Measuring SHC (liquid)

This uses a similar method to measuring the SHC of a metallic solid.

What additional factor must we consider?

The heat absorbed by the liquid's container (called a calorimeter).

## Electrical heater question

What are the advantages and
disadvantages of using paraffin rather
than water in some forms of portable
electric heaters?

## Advantages: <br> Electrical insulator - safer Does not corrode metal container Lower SHC - heats up quicker

Disadvantages:
Lower SHC - cools down quicker

### 11.3 Latent heat

This is the energy required to change the state of a substance. e.g. melting or boiling.
Draw a temperature - time graph to show the melting and vapourisation of water

## Task

The diagram shows the uptake of heat by 1 kg of water, as it passes from ice at $-50{ }^{\circ} \mathrm{C}$ to steam at temperatures above $100{ }^{\circ} \mathrm{C}$

Copy and label the diagram. Identify what is happening at each stage

## Answer

A: Rise in temperature as ice absorbs heat.

B: Absorption of latent heat of fusion.
C: Rise in temperature as liquid water absorbs heat.

D: Water boils and absorbs latent heat of vaporization.

E: Steam absorbs heat and thus increases its temperature.

## Specific latent heat, $l$

## What is specific latent heat ?

The specific latent heat, $l$ of a substance is the energy required to change the state of unit mass of the substance without change of temperature.

$$
\Delta Q=m l
$$

where:
$\Delta Q=$ heat energy required in joules
$m=$ mass of substance in kilograms
$l=$ specific latent heat in $\mathrm{J} \mathrm{kg}^{-1}$

## Examples of SLH

| Substance | State change | SLH (Jkg ${ }^{-1}$ ) |
| :---: | :---: | :---: |
| ice $\rightarrow$ water | solid $\rightarrow$ liquid <br> specific latent heat of fusion | 336000 |
| water $\rightarrow$ steam | liquid $\rightarrow$ gas / vapour <br> specific latent heat of vaporisation | 2250000 |
| carbon dioxide | solid $\rightarrow$ gas / vapour <br> specific latent heat of sublimation | 570000 |
| lead | solid $\rightarrow$ liquid | 26000 |
| solder | solid $\rightarrow$ liquid | 1900000 |
| petrol | liquid $\rightarrow$ gas / vapour | 400000 |
| mercury | liquid $\rightarrow$ gas / vapour | 290000 |

## Complete

| Substance | Change | SLH <br> $\left(\mathbf{J k g}^{-1}\right)$ | Mass | Energy (J) |
| :---: | :---: | :---: | :---: | :---: |
| water | melting | 336000 | 4 kg |  |
| water | freezing | 336000 | 200 g |  |
| water | boiling | 2.25 M |  | 9 M |
| water | condensing | 2.25 M | 600 mg |  |
| $\mathrm{CO}_{2}$ | subliming | 570 k | 8 g |  |
| $\mathrm{CO}_{2}$ | depositing | 570 k | 40000 rg |  |

## Answers

| Substance | Change | SLH <br> $\left(\mathbf{J k g}^{-1}\right)$ | Mass | Energy (J) |
| :---: | :---: | :---: | :---: | :---: |
| water | melting | 336000 | 4 kg | 1.344 M |
| water | freezing | 336000 | 200 g | 67.2 k |
| water | boiling | 2.25 M | 4 kg | 9 M |
| water | condensing | 2.25 M | 600 mg | 1350 |
| $\mathrm{CO}_{2}$ | subliming | 570 k | 8 g | 4560 |
| $\mathrm{CO}_{2}$ | depositing | 570 k | $40000 \mu \mathrm{~g}$ | 22.8 |

## Question

## Calculate

(a) the heat energy required to change 100 g of ice at $-5^{\circ} \mathrm{C}$ to steam at $100^{\circ} \mathrm{C}$.
(b) the time taken to do this if heat is supplied by a 500W immersion heater.

Sketch a temperature-time graph of the whole process. Stage 1 : ice at $-5^{\circ} \mathrm{C}$ to ice at $0^{\circ} \mathrm{C}$

## Answer (a)

```
Stage 1: Warm the water to \(0^{\circ} \mathrm{C}\)
\(\Delta Q=m \mathrm{c} \Delta \theta\)
\(=0.100 \mathrm{~kg} \times 2100 \mathrm{~J} \mathrm{~kg}^{-1}{ }^{\circ} \mathrm{C}-1 \times(0-(-5))^{\circ} \mathrm{C}\)
\(=0.100 \times 2100 \times 5\)
\(=1050 \mathrm{~J}\)
```

Stage 2: ice at $0^{\circ} \mathrm{C}$ to water at $0^{\circ} \mathrm{C}$
$\Delta Q=m l$
$=0.100 \times 336000$
$=33600 \mathrm{~J}$
Stage 3: water at $0^{\circ} \mathrm{C}$ to water at $100^{\circ} \mathrm{C}$
$\Delta Q=m c \Delta \theta$
$=0.100 \times 4200 \times 100$
$=42000 \mathrm{~J}$
Stage 4: water at $100^{\circ} \mathrm{C}$ to steam at

Stage 5:
Add them together:

$$
\begin{array}{r}
1050 \mathrm{~J} \\
+33600 \mathrm{~J} \\
42000 \mathrm{~J} \\
225000 \mathrm{~J} \\
\hline 301650 \mathrm{~J}
\end{array}
$$

```
100}\mp@subsup{}{}{\circ}\textrm{C
\DeltaQ=ml
=0.100 x 2 250000
= 225000 J
```

The heater supplies 500J per second to water. Assume no heat loss to the surroundings:

## (c) Sketch graph
